Arcodex

Launch on Arc. Trade in USDC.
Whitepaper v1.0
Arc Chain Launchpad · Native USDC
1% fee · 80/20 creator/platform split

Arcodex Whitepaper

Version 1.0 · Arc Chain Launchpad · Native USDC

Abstract

Arcodex is a memecoin launchpad built on the Arc blockchain, where **USDC is the native asset**. Every token launches on a bonding curve with a fixed **1% trading fee**, split **80% to the creator and 20% to the platform**. Arcodex aggregates tokens launched across all launchpads on Arc into a single discoverable marketplace with built-in swap.

1. Problem

Launching a token today is fragmented: multiple launchpads, inconsistent fee models, unclear creator economics, and no unified view of what exists on-chain. Creators cannot easily claim fees, and traders must jump between sites.

2. Solution

Arcodex provides:

- **One-click token launch** with two bonding types (Standard, Early Buy).
- **Native USDC pricing** everywhere - no ETH/WETH conversions, no price confusion.
- **Fixed 1% fee** with transparent 80/20 creator/platform split.
- **Unified token index** across all Arc launchpads with instant swap.
- **Bridge** for moving USDC onto Arc.
- **Liquidity pools** for post-graduation trading.

3. Bonding Curve

Tokens launch on a linear bonding curve:

```
price = startingPrice * (1 + sold / graduationThreshold)
```

- Price rises linearly as supply is purchased.

- At 100% graduation, remaining supply + curve USDC migrate to a full AMM pool.
- Early buyers are rewarded with lower prices; late buyers pay more.
- Curve liquidity is always backed 1:1 by USDC held in the contract.

Bonding Types

Type	Description
Standard	Linear curve, open to everyone from block one. Fair launch.
Early Buy	Whitelisted early buyers get first access before public trading.

4. Fee Model

Fixed **1.00%** fee on every trade (buy and sell):

Party	Share	Effective rate
Creator	80%	0.80%
Platform	20%	0.20%

- Fees accrue on-chain in USDC.
- Creators claim from their profile; the platform claims to a treasury wallet.
- No hidden fees. No gas token conversions - USDC is the native gas on Arc.

5. Architecture

6. Token Lifecycle

1. **Launch** - Creator deploys a token with metadata (name, symbol, description, website, socials).
2. **Bonding** - Traders buy/sell against the curve in USDC. 1% fee accrues.
3. **Graduation** - At 100% curve sold, liquidity migrates to a full AMM pool.
4. **Trading** - Post-graduation, the token trades freely on the AMM with the same 1% fee split.
5. **Claim** - Creator claims 80% of fees; platform claims 20%.

7. Security

- **Non-reentrancy guards** on all value-moving functions.
- **SafeERC20** for USDC transfers.
- **Ownable** admin functions (treasury, graduation).
- Curve liquidity is fully backed; no fractional reserves.
- Creator fees are claimable only by the designated fee wallet.
- Timelock/audit process before mainnet deployment.

8. Tokenomics

Item	Value
Trading fee	1.00% fixed
Creator share	80%
Platform share	20%
Price currency	USDC (native)
Curve graduation	100% of bonding supply

9. Roadmap

- **Phase 1** - Launchpad live (bonding curves, fees, claim).
- **Phase 2** - Token index across all Arc launchpads + unified swap.
- **Phase 3** - Bridge (LI.FI powered) + liquidity pools.
- **Phase 4** - Creator analytics, X integration, governance.

10. Disclaimer

Arcodex is a protocol for launching and trading community tokens. Tokens launched on the platform carry risk, including total loss. Nothing in this whitepaper is financial advice.
